

ICI Toxicity Phenotype Decomposition Across Evidence Systems

The answer to "Is ICI toxicity different between lymphoma and solid tumors?" depends on which phenotype and which evidence system is measured.

Phenotype Decomposition Model

Broad TRAE $\neq$ strict organ irAE $\neq$ pharmacovigilance reporting signals $\neq$ immune-signature associations.
Current evidence does not support intrinsic lymphoma-versus-solid lineage causality.
Future studies must specify the toxicity phenotype before estimating cross-tumor differences.

ICI toxicity is best treated as a decomposable phenotype space, not a single incidence endpoint.
